Education Gaps

Bronchopulmonary dysplasia (BPD) continues to affect a large portion of very low-birthweight infants; therefore, knowledge of the short- and long-term economic impact of BPD is necessary to gain a broader perspective of the disease.

Abstract

Despite significant technological advances and increasing survival of premature infants, bronchopulmonary dysplasia (BPD) continues to be the most prevalent major morbidity in surviving very low-birthweight infants. Infants with BPD are often sicker, require longer stays in the NICU, and accumulate greater hospital costs. However, care of the infant with BPD extends beyond the time spent in the NICU. This article reviews the costs of BPD in the health-care setting, during the initial hospitalization and beyond, and the long-term neurodevelopmental impact of BPD, as well as the impact on a family caring for a child with BPD.

Objectives  After completing this article, readers should be able to:

1. Describe the short- and long-term costs for infants with bronchopulmonary dysplasia (BPD).
2. Describe the impact of BPD on the health-care system.
3. Compare the costs of infants and children with BPD to those without BPD.
4. Discuss the impact of BPD on the child’s neurodevelopment.
5. Estimate the burden of BPD on the family unit.

INTRODUCTION

Approximately 1 in 10 infants is born prematurely in the United States. (1) In the year 2015 alone, there were more than 55,000 very low-birthweight (VLBW, <1,500 g) infant births. Although overall survival rates are improving, the number
of VLBW infants with at least 1 major morbidity remains high. (2) Bronchopulmonary dysplasia (BPD) was initially described as a disease of premature infants by William Northway, Jr, in 1967, when potential ventilator injury and oxygen toxicity were recognized as modifiable factors in ameliorating the disease process. (3) Although we have gained considerable understanding of the pathophysiology of BPD since that time, it continues to be the most prevalent major morbidity affecting an estimated 22% to 45% of all VLBW infants in the United States. (2)(4) This article reviews the resource utilization and costs of BPD and the impact on the health-care system and family.

**DIRECT MEDICAL COSTS AND HEALTH-CARE UTILIZATION**

**Birth Hospitalization**

VLBW infants account for a large percentage of birth hospitalization costs. In a population-based study in California, VLBW infants comprised 0.6% of all birth hospitalizations but accounted for 15.7% of total costs. (5) As infants with BPD tend to be sicker and smaller, the costs for caring for these infants are comparatively increased. In low-birthweight infants (<2,500 g), Russell et al found that the single most expensive cause of morbidity based on average cost per discharge was BPD; infants with BPD had an initial hospitalization cost that was 16 times higher than the cost of infants without BPD. (6) The median cost for NICU hospitalization for infants with BPD was $102,000 (US dollars, 2001) per infant compared to a median of $36,800 for all infants less than 28 weeks’ gestation age (GA) and $500 for uncomplicated newborns. Johnson et al found that in VLBW infants, BPD has the highest associated mean marginal costs compared to other significant morbidities (necrotizing enterocolitis, late-onset sepsis, brain injury). (7) The direct costs for those with BPD were 2.3 times higher than for those without BPD. Infants with BPD have significantly increased lengths of stay and hospitalization costs because of the greater number of procedures, greater duration of respiratory equipment use, and other advanced medical technologies in addition to increased risk of complications and comorbidities. (5)(8) These increased costs are reflected in prolonged hospitalization, with infants with BPD having an average length of stay 4 weeks longer, even after adjusting for birthweight and other risk factors. (9) Affected infants have an almost 6-fold increased risk of delayed discharge, defined as discharge after 42 weeks’ postmenstrual age. (10) Although there is tremendous variability in what is included in the cost accounting studies (eg, facility fees, hospital fees, etc), infants with BPD consistently pose a significantly higher economic burden on the health-care system across times and multiple studies (Table).

**The First 2 Years: Back to the Hospital and the Role of Respiratory Infections**

Respiratory illnesses are the number 1 reason for hospital readmissions in premature infants. (11) As BPD is known to be an underlying cause of pulmonary dysfunction, infants with BPD are susceptible to respiratory infections as well as increased severity of illness; thus, they are at greater risk for hospital admissions during an illness. (11)(12) Many studies have demonstrated that infants with BPD, particularly those with moderate to severe BPD, have a significantly higher rate of rehospitalization for respiratory causes. (8)(11)(12)(13) In a population-based study of almost 1,600 infants at less than 33 weeks’ GA, infants with BPD had increased rehospitalization rates during the first year of age (49%) compared with infants without BPD (23%). (8) Furthermore, there were significant differences in number of readmissions as well as length of stay during those subsequent hospitalizations.

A significant health-care burden for patients with BPD is respiratory syncytial virus (RSV). Although RSV often causes a self-limited respiratory infection for most infants, it is a leading cause of hospitalization in the first year for all infants, with rates of hospitalization reported at 16.9 per 1,000 infants of age 0 to 5 months and 5.1 per 1,000 infants of age 6 to 11 months. (14) It is recognized that BPD is a major independent risk factor for RSV disease leading to serious infections and hospitalizations. (15) Infants born preterm with BPD may be particularly vulnerable to RSV because of their history of underdeveloped or injured alveoli, pulmonary vasculature, and respiratory epithelium, which predisposes them to pulmonary edema with infection. (16) RSV infection in the context of BPD has been shown to lead to increased likelihood of hospitalizations, hospital length of stay, ICU admission, and need for mechanical ventilation. (17)(18)(19) Patients with BPD with RSV infections also have increased outpatient visits and higher total cost of care for the first 2 years of age. (20) A history of RSV infection in patients with BPD has a downstream effect on patient morbidity, leading to continued increased health-care utilization (outpatient visits, cost of care) at 5 to 7 years of age and also significantly worse pulmonary function at 8 to 10 years of age. (21) Palivizumab, a mouse monoclonal antibody product directed against an RSV protein, has been shown to be effective in reducing the burden of hospitalization in preterm infants, with RSV-related hospitalizations in preterm infants with BPD decreasing from 12.8% to 7.9%. (22) However, palivizumab
remains an expensive therapy to administer and cost-effectiveness for various populations remains in question, though a stronger case can be made for preterm infants with BPD. (23)

Beyond the Second Year: Rehospitalizations and Outpatient Visits
Rehospitalization rates in patients with BPD continue to be comparatively higher beyond the initial year with an increased risk for rehospitalization and more frequent outpatient visits. (13) Although most infants will not require oxygen beyond 2 years of age, indicating clinical improvement, up to 25% will continue to have respiratory complications into young adulthood. (12)(24) Children and adolescents with a history of BPD are more often diagnosed with asthma (26.9% vs 11.8%; P<.0001) and psychiatric illnesses (such as depression, anxiety, attention-deficit/hyperactivity disorder) leading to increased health-care utilization. (25) In a Quebec study comparing a preterm BPD cohort and a preterm respiratory distress syndrome cohort over 16 to 25 years, the costs of medical services and total health-care costs per person annually was significantly increased in the BPD cohort ($13,472 vs $10,719; P=.02; expressed in 2008 Canadian dollars). (25)

Durable Medical Equipment
In a multicenter study, approximately one-third of infants with BPD of any severity were sent home with oxygen

*Continued*
supplementation. (24) Infants categorized with either moderate or severe BPD likely account for most of these cases, as they are discharged with oxygen supplementation 57% to 68% of the time. (31)(32) It is important to note that home oxygen use is largely institution dependent, with a large study of 117 centers finding that home oxygen use ranged from 7% to 95% in infants requiring respiratory support at 36 weeks’ postmenstrual age. (32) Infants who were oxygen dependent had outpatient visits, specialist visits, and prescription costs approximately 3 times greater than infants sent home without oxygen from 2 to 4 years of age. (24) As most children no longer required continuous supplemental oxygen beyond the second birthday, this represents a continued increased health-care cost and respiratory morbidity beyond just receiving oxygen supplementation. These differences in health-care utilization continued through school age. (33)

Given that prolonged ventilation plays a significant role in the development of BPD, infants with severe BPD are at increased risk for tracheostomy placement with or without ventilator dependence. Tracheostomy may be a result of pulmonary disease that is dependent on positive pressure ventilation, consequences of prolonged intubation (such as subglottic stenosis, vocal cord paralysis, granulation tissue), or airway anomalies (such as laryngotracheomalacia). A large multicenter study found that 0.1% of all NICU infants required a tracheostomy over a 16-year period, with BPD

being the number 1 diagnosis associated with the procedure (45%). (34) Another study from 27 centers found that 13.5% of infants with severe BPD required a tracheostomy and 20.4% of infants with severe BPD required a tracheostomy or died before discharge. (35) Infants with tracheostomies are either discharged from the hospital or sent to a care facility after receiving extensive family education and multidisciplinary care coordination by the medical team to ensure safety. Once a tracheostomy is placed, the median time to decannulation was 436 to 479 days (range 48–1,611 days). (36) Furthermore, health-care utilization in the 5 years following tracheostomy placement in children is increased, including total time of hospitalization (mean±SD, 32.3±65.9 days) and risk of at least 1 readmission within 30 days (45.1%). (37) The use of technology can increase both direct medical costs (equipment, supplies, nursing care, outpatient visits, hospitalizations, prescriptions) and nondirect costs (electricity, water, family stress, loss of income).

**BPD AND CHILD NEURODEVELOPMENT**

Numerous studies have found that BPD is an independent risk factor for poor developmental outcomes, low IQ, and cerebral palsy. (12)(38) Children with moderate to severe BPD have a lower developmental quotient and more developmental disabilities (defined as developmental quotient less than 2 SD below mean, severe cerebral palsy, bilateral blindness, or severe hearing deficit) compared to those with or without mild BPD. (39) Infants with BPD often have more prolonged periods of hypoxemia, or apnea, associated with the need for increased ventilator days compared to peer infants without BPD. This severity of illness likely affects brain development of the premature infant. In cases of severe BPD, movement disorders similar to chorea and akathisia have been described as early as the third month of age with an autopsy in 1 patient demonstrating hallmarks of hypoxic brain injury. (40) Moreover, infants with BPD have poor physical growth compared to peers with lower mean weight and head circumference. (38)(41) Thus, the effects of BPD on neurodevelopment is likely multifactorial, related to underlying pathophysiology of BPD, growth failure, and environmental factors (such as socioeconomic status and parental education).

The delay in neurodevelopment can be detected early with a significantly increased number of infants with BPD having sensorineural conductive hearing loss compared to controls requiring tympanostomy tube placement (22.1% vs 7.7%). (42) Another study demonstrated that at 10 months of age, infants with BPD had poor hand-eye coordination and perception and intelligence compared to infants with mild BPD or without BPD. (43) These differences persisted at age 5.5 years with poor visual-spatial development along with deficits in cognition. (44) Deficits are also apparent in language development as infants with BPD have lower receptive language skills starting at 3 years of age with increased enrollment in speech and language therapy by 8 years of age compared to peers without BPD. (45) By school age, children with BPD were more likely to be enrolled in special education classes with deficits in reading, mathematics, and gross motor skills, even after correcting for neurologic risk factors. (46) Greater severity of BPD was also associated with lower school achievement, lower IQ, increased therapy needs (occupational, physical, speech), and special education enrollment. In particular, those requiring a tracheostomy had significantly more adverse developmental outcomes. (47) With these complications, it is not surprising that adults with a history of preterm birth and BPD were less likely to have access to higher education and more likely to be unemployed. (48)

In an estimate by the Centers for Disease Control and Prevention, average lifetime costs for 4 different developmental disabilities (mental disabilities, cerebral palsy, hearing loss, and vision impairment) ranged from $417,000 to $1,014,000 (2003 US dollars) per person. (49) As individuals with BPD are at higher risk of being affected by these disabilities both through childhood and as adults, the economic costs continue to be comparatively increased throughout their lifetime. The report further specifies that lifetime indirect costs (ie, productivity losses, decreased functional participation) reflects up to 81% of total lifetime costs. When looking at direct medical expenditures alone, children who have more than 1 disability will have substantially higher associated costs. In a comparison of children with cerebral palsy, those who also had intellectual disability had 1-year mean medical expenditures 2.5 times the amount of those with a single diagnosis of intellectual disability or cerebral palsy. (50) Even with 1 diagnosis, the mean medical expenditure in 1 year was 10 times higher than the control population without cerebral palsy or intellectual disability.

**FAMILY BURDEN**

Studies have shown that there are increased parental stressors when an infant is born premature or with low birthweight. (51)(52) Psychological distress is mainly manifested as symptoms of depression, anxiety, and posttraumatic stress both during and after a NICU admission. (52) Up to 40% of mothers of very preterm infants report significant depression based on the Edinburgh Postpartum Depression
Scale compared to 10% to 15% of postpartum women overall. (53) As BPD infants tend to have more complications and a prolonged hospitalization, mothers of infants with BPD often have more severe negative symptoms. Caregivers are also more likely to have negative symptoms during the first 2 years of age if the child is frequently ill, and requires more outpatient visits and health-care utilization. (54) Studies have shown that personal, family, and financial stressors are more pronounced when the school-age child has lower IQ scores and more severe neurodevelopmental outcomes. (55)(56) In a prospective longitudinal study Singer et al compared mothers of VLBW infants with BPD, VLBW infants without BPD, and term infants from birth through adolescence. (56)(57) Over time, mothers of VLBW infants with BPD had increased personal, family, and financial stress, as well as lower attainment of additional education, whereas mothers of VLBW infants without BPD had similar outcomes to term mothers in most categories. Financial stressors can be a direct result of loss of wages, with up to 42% of families of infants with BPD discharged with oxygen supplementation losing wages in order to provide home medical care to their child. (30) Financial strain directly affects parental stress, with familial socioeconomic status being a significant risk factor for greater stress for any family independent of the child’s health status or IQ. (56)

The impact on the family is best portrayed from the parents’ own experience. As part of understanding the family burden of NICU parents, one of the coauthors (A.N.) led a video project to highlight the NICU parent perspective. Parents talked about what life is like with their children years after the NICU. In this 6-minute video (https://youtu.be/TRGKWm2DBbA), the impact of having a former premature infant with special health-care needs is communicated eloquently and clearly by the family (Fig).

CONCLUSIONS AND IMPLICATIONS

BPD is the most prevalent major morbidity in surviving VLBW infants. The economic burden stems from increased health-care costs starting with the birth admission and persists through childhood and into adulthood. The costs are increased both in a setting of relatively routine disease states (eg, RSV infection), as well as with disease severity (eg, patients with tracheostomies). In addition, there is a significant impact on the family unit of patients with BPD, with respect to both psychosocial and financial stressors. The burden of BPD that is imposed on the health-care system and the family, in combination with the association of BPD and worse neurodevelopmental outcomes, produces a substantial cumulative societal cost. When considering strategies in BPD reduction (ie, delivery room interventions, lung protective ventilation approaches, novel medications, quality improvement interventions), the return of investment calculus should take into account the annual economic impact of 12,100 infants diagnosed with BPD (22% of VLBWs, low estimate) per year in the United States and their lifetime “cost” to those individuals and their families, health-care system, and society.

There are two ways to access the journal CME quizzes:
1. Individual CME quizzes are available via a handy blue CME link in the Table of Contents of any issue.
2. To access all CME articles, click “Journal CME” from Gateway’s orange main menu or go directly to: http://www.aappublications.org/content/journal-cme.

NOTE: Learners can take NeoReviews quizzes and claim credit online only at: http://Neoreviews.org.

To successfully complete 2018 NeoReviews articles for AMA PRA Category 1 Credit™, learners must demonstrate a minimum performance level of 60% or higher on this assessment, which measures achievement of the educational purpose and/or objectives of this activity. If you score less than 60% on the assessment, you will be given additional opportunities to answer questions until an overall 60% or greater score is achieved.

This journal-based CME activity is available through Dec. 31, 2020, however, credit will be recorded in the year in which the learner completes the quiz.

NeoReviews Quiz

1. Your NICU is forming a multidisciplinary team specifically focused on the care of the very preterm neonate. As you plan for resource allocation, you are reviewing studies on very low-birthweight infants. Which of the following morbidities experienced by these infants has been associated with the highest mean marginal cost?
   A. Intraventricular hemorrhage.
   B. Bronchopulmonary dysplasia (BPD).
   C. Late-onset sepsis.
   D. Necrotizing enterocolitis.
   E. Brain injury.

2. A 25-week gestational age infant is nearing discharge after a prolonged initial NICU stay. The infant was diagnosed as having BPD at 36 weeks’ postmenstrual age, but is now breathing room air. As you counsel the parents on what to expect in the coming months, they ask about the possibility of rehospitalization. Which of the following statements regarding preterm infants and hospital readmission is correct?
   A. Respiratory illnesses are the number 1 reason for hospital readmissions in preterm infants, and patients with BPD are at higher risk for such readmissions.
   B. Although prolonged NICU hospitalizations are not desirable, a benefit of a long hospital course in very preterm infants is that their risk of readmission within the first year is lower than that for term or late preterm infants.
   C. Although preterm infants are just as likely to have illnesses that might lead to hospitalization, the rates of hospital readmission in the first year are similar to or less frequent than term infants, due to parental avoidance of the health-care system.
   D. BPD is not an independent risk factor for increased readmission during the first year after birth.
   E. The main reason for readmission in infants with BPD is patent ductus arteriosus ligation.

3. As a premature infant is getting ready for discharge, you are counseling the parents about the potential benefits of palivizumab for respiratory syncytial virus (RSV) prophylaxis. Which of the following statements regarding this practice is correct?
   A. RSV has a consistent risk profile for both term and preterm infants during the first year, with similar rates of hospitalization during each month after birth.
   B. Although RSV infection can be more serious in infants with BPD, hospitalization for an RSV infection is now rare, because of the growing efficacy of herd immunity from vaccinations.
   C. It is recognized that BPD is a major independent risk factor for RSV disease leading to serious infections and hospitalizations.
   D. Although RSV infection can cause serious illness in infancy, there are no associated long-term effects, other than recurrent wheezing which may last up to about 3 years of age.
   E. Palivizumab is recommended for all preterm infants of less than 34 weeks’ gestational age regardless of whether there was a history of BPD.

4. A female infant born at 25 weeks’ gestational age is now 2 years old and being seen in the follow-up clinic. The infant had a history of BPD and went home receiving oxygen therapy, but oxygen therapy was discontinued since 6 months of age. She is now meeting developmental milestones, with no hospitalizations in the past year. Which of the following statements regarding this and similar patients is correct?

2018 NeoReviews now is approved for a total of 10 Maintenance of Certification (MOC) Part 2 credits by the American Board of Pediatrics through the ABP MOC Portfolio Program. Complete the first 5 issues or a total of 10 quizzes of journal CME credits, achieve a 60% passing score on each, and start claiming MOC credits as early as May 2018.
A. This patient is not truly categorized as having BPD, because she does not require oxygen at 2 years of age.

B. Children with a history of BPD are more often diagnosed with asthma and psychiatric illnesses such as depression and anxiety.

C. Rates of readmissions to the hospital and outpatient visits for patients with BPD become similar to the general population after the first year.

D. In most population-based cohort studies, up to 75% of patients diagnosed with BPD in the NICU will require oxygen again in childhood after they turn 2 years old.

E. By young adulthood (~18 to 22 years of age), the rates of respiratory complications in patients who had BPD are less than 5%.

5. An infant born at 25 weeks’ gestational age has BPD and is now 4 months old in the NICU. He continues to require oxygen therapy, with occasional need for positive pressure ventilation. As you are discussing further management, you discuss the possibility of tracheostomy. Which of the following statements regarding supplemental oxygen and other therapies for patients with BPD is correct?

A. Although tracheostomy is a relatively common procedure in the NICU (~10% of all patients), it is relatively less common for patients with BPD (~1% of infants with severe BPD) because of the transient nature of the disease.

B. Tracheostomy may be a result of pulmonary disease dependent on positive pressure ventilation, consequences of prolonged intubation (such as subglottic stenosis, vocal cord paralysis, granulation tissue), or airway anomalies (such as laryngotracheomalacia).

C. Most tracheostomies for this condition are short-lived, with median time to decannulation being 30 to 45 days, depending on the cohort.

D. Health-care utilization in the 5 years after tracheostomy placement is less than that among those who do not receive tracheostomy, due to the benefit of relative stability of airway management and decreased need for acute care hospitalization.

E. Although there is an added immediate cost for the procedure of tracheostomy, there is generally an overall cost savings in early infancy (~0 to 5 years of age) for both direct and indirect costs, due to reduction in readmission after the procedure.
